AB The authors describe herein a detection and quantification system for on-chip phosphorylation of **peptides** by surface plasmon resonance (SPR) imaging techniques using a newly synthesized phosphate capture mol. (i.e., biotinylated zinc(II) complex). The biotinylated compound is a dinuclear zinc(II) complex that is suitable for accessing phosphate anions as a bridging ligand on the two zinc(II) ions. The compound was exposed on the **peptide** array and detected with streptavidin (SA) via a **biotin**-SA interaction by SPR imaging. In the conventional method using antibody, both anti-phosphoserine and anti-phosphotyrosine antibodies were required for phosphoserine and phosphotyrosine detection, resp. Detection of the phosphate group by the zinc(II) complex, however, was independent of the phosphorylated amino acid residues. The calibration curve for the phosphorylation ratios was established with a calibration chip, on which phosphoserine-containing **peptide** probes were immobilized. The **peptide** probes, which were phosphorylated on the surface by protein kinase A, were detected and quantified by SPR imaging using the zinc(II) complex, SA, and anti-SA antibody. The reaction rate and the kinetics of on-chip phosphorylation were also evaluated with the **peptide** array. The phosphorylation ratio was saturated at .apprx.20% in 2 h in this study.

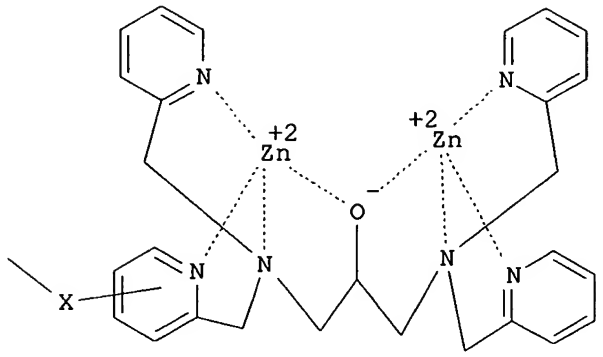
GI



I

AB A method of measuring a surface plasmon resonance, in which the presence of phosphorylated **peptide** (protein) can be easily detected from a biosample or the like and in which whether or not **peptides** are phosphorylated can be judged; and a noble metal compound that exhibits high capability of coordinate bonding with phosphorylated **peptides** to thereby enable suitable use in this method. There is provided a 1st method of measuring a surface plasmon resonance, comprising disposing a noble metal compound on a prism bottom surface, exposing the prism to light and detecting any reflected light, wherein as the noble metal compound, one having a substituent I is employed on the side opposite to the side in contact with the prism and wherein in the noble metal compound, a test specimen is added to the side having the substituent I [X = **linker** group to noble metal].

AB A method is provided for not only confirming the presence of a compound having been converted to a phosphoric acid monoester (e.g., **peptide**, carbohydrate) even with respect to, for example, any biol. sample containing multiple compds., but also easily measuring the mol. weight of the phosphoric acid monoester compound Also provided is an additive for mass spectrum measurement used in this method. The method comprises obtaining multiple mass spectrum data using a coordination compound which exhibits the extremely high coordination capacity for a phosphoric acid monoester group and is constituted with a single zinc isotope (e.g., 64Zn, 68Zn, natural isotope Zn), and comparing them with each other.

AB A trapping agent for a substance having an anionic substituting group is provided, which is a polymer support capable of trapping an anionic substituting group (e.g., phosphate group) by possessing the property of binding with the anionic substituting group (e.g., phosphate group) under a certain condition. The polymer support is sparingly solvent-soluble, preferably solvent-insol., as a whole, and a specific zinc coordination group which is easily separated and purified. is bound to it by a covalent bond directly or through a spacer.

AB Provided are a method for easily detecting phosphorylated **peptides**, namely, proteins, in samples derived from living organisms or the like, a method for selectively adsorbing the phosphorylated **peptides**, and compds. that are highly coordinated to the phosphorylated **peptides** and usable in the methods. The complex compound is represented by the formula: wherein X is a **linker** moiety, and Y is a **labeling** group. The compound (I) is highly coordinated to a phosphorylated **peptide**. and has a **labeling** group. Accordingly, with use of the compound (I), the phosphorylated **peptide** can be easily identified.

AB   A method and a reagent are provided for conveniently regulating an enzymic
     activity (e.g., glucose dehydrogenase) without causing the inactivation of
     the enzyme.  The method for regulating an enzymic activity is
     characterized in that a chelating compound (e.g., polyamine-zinc
     complex) is brought into selectively and reversibly binding to the
     monoester phosphoric acid part of a coenzyme (e.g., NADP).  Also provided
     is a method for enzymically measuring a substance (e.g., inorg.
     phosphorate), which is characterized in that a chelating compound is brought
     into selectively and reversibly binding to the monoester phosphoric acid
     part of a coenzyme.  Also provided is a reagent for enzymically measuring
     a substance, which contains at least a cofactor, an enzyme, substrate, and
     a chelating compound capable of selectively and reversibly binding to the
     monoester phosphoric acid part of the coenzyme.

AB Recognition of phosphate monoester dianion by an alkoxide-bridged dinuclear **zinc**(II) complex (Zn2L3+) has been studied (L = alkoxide species of 1,3-bis[bis(pyridin-2-ylmethyl)amino]propan-2-ol). Potentiometric pH titration study disclosed a 1:1 Ph phosphate complexation with Zn2L3+ in aqueous solution The dissociation constant (= [Zn2L3+][PhOPO32-]/[Zn2L3+-PhOPO32-]) is an extremely small value of 2.5 + 10-8 mol dm-3 at 25 °C with I = 0.10 (NaNO3). The X-ray crystal anal. of the dizinc(II) complex with p-nitrophenyl phosphate showed that the phosphate dianion binds as a bridging ligand to the two **zinc**(II) ions.

AB Dizinc complexes that were formed from 2 : 1 mixts. of **Zn**(NO3)2 and dinucleating ligands TPHP (1), TPmX (2) or TPpX (3) in aqueous solns. efficiently hydrolyzed diribonucleoside monophosphate diesters (NpN) under mild conditions. The dinucleating ligand affected the structure of the aquo-hydroxo-dizinc core, resulting in different characteristics in the catalytic activities towards NpN cleavage. The pH-rate profile of ApA cleavage in the presence of (Zn2+)2-1 was sigmoidal, whereas those of (Zn2+)2-2 and (Zn2+)2-3 were bell-shaped. The pH titration study indicated that (Zn2+)2-1 dissocs. only one aquo proton (up to pH 12), whereas (Zn2+)2-2 dissocs. three aquo protons (up to pH 10.7). The observed differences in the pH-rate profile are attributable to the various distributions of the monohydroxo-dizinc species, which are responsible for NpN cleavage. As compared to that using (Zn2+)2-1, the NpN cleavage using (Zn2+)2-2 showed a greater rate constant, with a higher product ratio of 3'-NMP/2'-NMP. The saturation behaviors of the rate, with regard to the concentration of NpN, were analyzed by Michaelis-Menten type kinetics. Although the binding of (Zn2+)2-2 to ApA was weaker than that of (Zn2+)2-1, (Zn2+)2-2 showed a greater kcat value than (Zn2+)2-1, resulting in higher ApA cleavage activity of the former.

AB The binuclear **zinc**(II) complex, [Zn2(HPTP)(CH3COO)]2+ was found highly active to cleave DNA (double-strand super-coiled DNA, pBR322 and ϕ+174) in the presence of hydrogen peroxide. However, no TBARS (2-thiobarbituric acid reactive substance) formation was detected in a solution containing 2-deoxyribose (or 2'-deoxyguanosine, etc); where (HPTP) represents N,N,N'-N'-tetrakis(2-pyridylmethyl)-1,3-diamino-2-propanol. These facts imply that DNA cleavage reaction by the binuclear **Zn** (II)/H2O2 system should be due to a hydrolytic mechanism, which may be attributed to the enhanced nucleophilicity but depressed electrophilicity of the peroxide ion coordinated to the **zinc**(II) ion. DFT (d.-functional theory) calcns. on the peroxide adduct of monomeric **zinc**(II) have supported the above consideration. Similar DFT calcns. on the peroxide adducts of the Al(III) and La(III) compds. have revealed that electrophilicity of the peroxide ion in these compds. is strongly reduced. This gives an important information to elucidate the fact that La3+ can enhance the growth of plants under certain conditions.

AB A trinuclear **Zn**(II) complex is newly prepared using a ligand having six pyridine moieties, N,N,N',N',N'',N''-hexakis(2-pyridylmethyl){tris-(2-aminoethyl)amine} (L1). The trinuclear **Zn**(II)3-L1 complex efficiently hydrolyzes diribonucleotides at pH 7 and 50 °C; its activity is much greater than that of a dinuclear (**Zn**(II))2-(1,3-bis[bis(2-pyridinylmethyl)amino]-2-propanol) complex. The hydrolysis by the trinuclear **Zn**(II)3-L1 complex is also unique in the product ratio; highly selective over the 2'-monophosphate is observed

AB Dinuclear **Zn**(II) and La(III) complexes with TPHP efficiently hydrolyze a dinucleotide, ApA, under mild conditions (TPHP = N,N,N',N'-tetrakis[(2-pyridyl)methyl]-2-hydroxy-1,3-diaminopropane). [Zn2(TPHP)]3+ hydrolyzes ApA with an extremely high activity; the pseudo-first-order rate constant is 8.4 + 10-4 h-1 at pH 7, 50° when [[Zn2(TPHP)]3+] = 2.5 mM. Free **Zn**(II) ion shows no hydrolysis activity under the conditions. Enormous acceleration of the hydrolysis by the dinuclear complex formation was also observed for La(III) ion. Its activity for the ApA hydrolysis is 100-fold greater than that of free La(III) ion. These dinuclear complexes are promising for the active sites of artificial RNases.

AB A dinuclear **zinc**(II) complex with N,N,N',N'-tetrakis[(2-pyridyl)methyl]-2-hydroxy-1,3-diaminopropane efficiently hydrolyses ApA [adenylyl(3'-5')adenosine] at pH 7 and 50°C; the complex can thus be regarded as a good artificial RNase which effectively mimics enzyme active sites.

AB The authors describe herein a detection and quantification system for on-chip phosphorylation of peptides by surface plasmon resonance (SPR) imaging techniques using a newly synthesized phosphate capture mol. (i.e., biotinylated zinc(II) complex). The biotinylated compound is a dinuclear zinc(II) complex that is suitable for accessing phosphate anions as a bridging ligand on the two zinc(II) ions. The compound was exposed on the peptide array and detected with streptavidin (SA) via a biotin-SA interaction by SPR imaging. In the conventional method using **antibody**, both anti-phosphoserine and anti-phosphotyrosine **antibodies** were required for phosphoserine and phosphotyrosine detection, resp. Detection of the phosphate group by the zinc(II) complex, however, was independent of the phosphorylated amino acid residues. The calibration curve for the phosphorylation ratios was established with a calibration chip, on which phosphoserine-containing peptide probes were immobilized. The peptide probes, which were phosphorylated on the surface by protein kinase A, were detected and quantified by SPR imaging using the zinc(II) complex, SA, and anti-SA **antibody**. The reaction rate and the kinetics of on-chip phosphorylation were also evaluated with the peptide array. The phosphorylation ratio was saturated at .apprx.20% in 2 h in this study.
